

NY4

There are many examples of pollinators and what they do for us.

Pollinators help us have beef, vegetables and even fruits like bananas. The pollinators go into the plant's stigma and go down into the ovary to get the pollen. They get pollen from the anthers, too. The pollinators help crops grow like corn, beans, carrots and tomatoes.

There are many different types of pollinators in nature. We have different pollinators like hummingbirds and honey bees. The hummingbird puts its beak into the pistil and gets the pollen out. The bees rub up against the anther and the nectar falls off. Pollinators are very important because of the food that we have today. There are a lot of things that we would not have without pollinators.
